The process of image manipulation Photoshop can be used to manipulate an image in a variety of ways. Figure 3.8 shows how to work in a grayscale photograph. In Figure 3.8A, the image of a pine tree appears on screen. It looks like a pleasant still image. Figure 3.8 Work with a grayscale image. Figure 3.8A The original image. Figure 3.8B Use the Edge Detection settings to add a watercolor texture to the pine tree. Figure 3.8C The image after watercolor editing. In Figure 3.8B, I've turned on the Watercolor Filter and smeared the texture. In Figure 3.8C, I've applied the Watercolor Filter settings to the entire image and changed the mode to Multiply. Now the entire image is darkened. In Figure 3.8D, I've adjusted the Levels tool to lighten the image. I'm going to use Levels again. The Levels tool makes it easy to lighten and darken an image. You can change the levels between light and dark either by adjusting the amount of black and white in the image or by increasing the contrast. Figure 3.8D The levels tool. Figure 3.8E Darken the image even more by adjusting the levels, changing the image mode to Overlay, and removing the Watercolor Filter settings. You can control the effect of the Levels tool even more by changing the mode in which it operates. One of the modes is to overlay one image over another. By blending between the two images, you can find a balance between light and dark. One of the options in the Levels dialog box is shown in Figure 3.8F. When you select Overlay, the image in the second column blends with the image in the third column and you can control the effect of

Spatial attention and scene representation of art-viewing: Evidence from a mental imagery task. The meaning of art resides in the way we represent a visual scene to ourselves, integrating it with our memories, emotions and personality. We can carry out tasks of mental imagery of works of art (MAIs), that is, perform imaginary mental manipulation of the scene that the work represents. However, it is still unknown whether these kinds of mental representations have different characteristics from actual experiences of viewing art, or whether the spatial features of mental representations are similar to the spatial characteristics of the artworks themselves. The goal of the present study was to investigate the neuropsychological representation of paintings by means of MAIs. In particular, we examined whether the MAIs of a painting are made through mental representation of its spatial features or whether the spatial representation is instead spatially coherent. We measured the gaze positions of the participants in the viewing condition (as they viewed a computer-generated, interactive, original painting by Uesugi, "Five Paths in Shibuya") and in the MAI condition (in which they were asked to imagine mentally the same painting). Our data show that the MAI and viewing conditions differ, but spatial coordination of mental representations is greater than the spatial coordination of images themselves, suggesting that mental representations have strong spatial aspects, even if they are far from being veridical experience.Q: Cauchy's Integral Formula on a subset of $[0,\infty)$ If we take a complex function $f(z)$ on a set $D\subseteq \mathbb{C}$ and D is a subset of the plane then the definition of the integral and the Cauchy Integral Theorem says that if D is bounded then the integral and Cauchy integral are the same. But what if D is only a subset of the plane? Can we still use the Cauchy Integral Theorem? If so, does the same hold on a countably infinite union of domains in the plane, $D=\bigcup_{i=1}^\infty D_i$? A: Any bounded domain $D \subset \mathbb{R}^2$ admits a "Radon measure" in the sense of Amérys Tenenbaum: Introduction to analytic and probabilistic number theory, Exercises 3.4.3. And
